Abstract

The turbo-pump machinery used to feed propellant from the external tank of the Space Transportation System into the Space Shuttle Main Engines is a costly and complex system. One method by which to reduce this cost and complexity is to develop a pressure fed propellant system. This paper investigates the feasibility of utilizing a pressurant system as a means to feed propellant to the Space Shuttle Main Engines. This investigation addresses a situation as simple as replacing the turbo pumps with a pressurant tank to more complex situations of staging the Shuttle launch system to reduce needed propellant. The results of this investigation are not as optimistic as first anticipated. From the top-level analysis, a pressure fed system is highly unfeasible as well as impossible. This is a result of the current tank technology as well as the physics of the situation.

1.0 Introduction

The Space Transportation System (STS), or Space Shuttle, is both a complex and costly device for inserting payloads into space. The propellant feed system for the Space Shuttle Main Engines (SSME's) is no exception. To provide the necessary thrust and specific impulse for lift-off and orbit insertion, the SSME's utilize turbo pumps to furnish the essential pressures and mass flow rates of the oxidizer and fuel. This method of feeding propellants to liquid rocket engines is both complex and costly. Turbo pumps contain many high speed moving parts at high temperatures. The complexity of moving parts compounded by high speeds and high temperatures adds to the risk of failure as well as to the cost of high maintenance.

To remedy this cost and complexity, a pressure fed system is being proposed to replace the current pump system. A pressure fed system consist mainly of pressure valves and propellant and pressurant tanks. These objects are passive in nature and as a result, contain little or no moving parts. This reduces the overall complexity, cost, and risk of the STS mission. In attempt to minimize new design and testing which will restrain the costs, the proposed system utilizes as much of the current system as possible. In addition, the investigation will look at the capability of launch system reusability, including any large external propellant tank.

2.0 Background

2.1 Space Transportation System

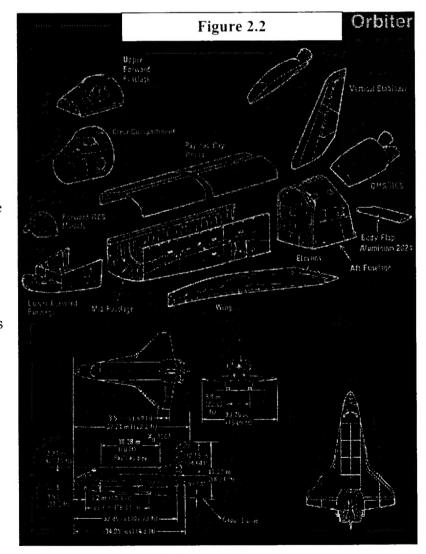

Before altering and modifying the Space Transportation System, a better understanding of the current system is essential. The following section addresses the basic vocabulary, elements, and subsystems of the current system.

The Space Transportation System (STS) consists of three main segments, the orbiter, external tank (ET), and solid rocket motors/boosters (SRM SRB). Each system works together in

parallel fashion to allow the launch system to achieve orbit insertion.

2.1.a Orbiter

The orbiter (Figure 2.2, Table 2.2) is the principal element of the STS and is designed to last approximately 100 flights [1]. This winged vehicle is both an aircraft and a spacecraft; acting as a spacecraft during launch and on-orbit operations, and as a

aircraft while performing an unpowered descent back to Earth. While the exact values for

ORBITER (Table 2.2)			
m _{orb tot} (empty) (kg)	75,000.00

length (m)	37.24		

orbiter dimensions and payload capabilities vary between each orbiter (i.e. Enterprise, Columbia, Atlantis, etc.) the following are approximate values obtained from the Space Shuttle Operator's Manual [1] and can be viewed in Table 2.2. The orbiter has the capability of carrying a 4.5-by-18-meter

payload with a mass up to 29,500 kg (Table 2.2) into an approximate 300km, 28.5-57 degree inclination orbit. It has a wingspan of 24 meters, a height—including landing gear—of 17.25 meters, and length of 37.24 meters.

2.1.b **SSME**

This vehicle also houses one of the main elements of concern throughout this paper, the three Space Shuttle Main Engines (SSME's). This element of the orbiter is one of the most crucial to this paper. Values and terms mentioned below are referred to throughout this paper, specifically in sections 3-5. The values of greatest interest are the chamber pressure, thrust, and specific impulse.

The SSME's (Figure 2.3, Table 2.3) are the most advanced liquid fueled engines ever developed and are currently a product of the Rocketdyne division of Boeing. The SSME's have a 100% flight success rate with a demonstrated reliability of over .999 [3]. The SSME is a reusable staged-combustion cycle engine, using a 6-to-1 liquid oxygen (LOX) and liquid

hydrogen (LH) mixture to fuel the engine. Its main features include variable thrust and regenerate cooled nozzle and combustion chamber (fuel runs through tubes in the nozzle and combustion chamber wall to transfer heat from the nozzle and chamber to the fuel), and vector

thrusting (gimballed engine). The engine has the capability of producing 2,174,286 Newtons (488,000 lbs) of thrust at a 104% power rating, 1,734,803 Newtons (390,000 lbs) at sea level [4]. It also has a maximum thrust capability of 2,278,824 Newtons (512,300 lbs) at a 109% power rating for emergency purposes. The SSME's operate with an chamber pressure of 22,614,804 Pa (3280 psia), which is the major driving factor for this

project, and a total mass flow rate of 487.12 kg/s. In addition, the SSME contains a bell shaped nozzle with an expansion ratio (ε) of 77.5:1 and exit diameter of 2.44 m. Currently, the engines feature high performance turbo pumps to boost the propellant pressure and mass flow rate which is covered in section 2. Of greatest concern is the required chamber pressure and mass flow rate necessary for the engines to produce the aforementioned thrust and specific impulse of 454.5 seconds.

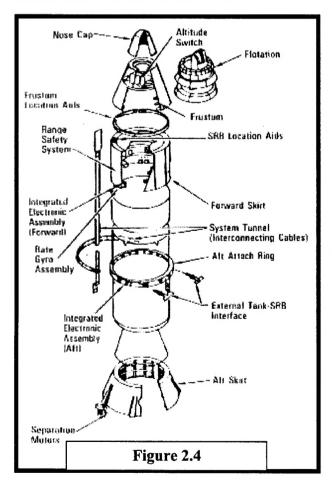

$$Isp = \frac{F}{mg_o}; g_o = 9.81 \frac{m}{s^2}$$

$$F = thrust \qquad ; \text{ (equation 2.1)}$$

$$m = mass \quad flow \quad rate$$

Specific impulse, equation 2.1, is a common performance parameter which compares the thrust derived from a system as a function of the propellant mass flow rate [5]. Because of turbo pump limitations with mass flow rates and pressure rise, the thrust, based off of equation 2.1, of the SSME is greatly limited to the aforementioned maximum value of 2,278,824 Newtons. As a result of this low thrust, the 3 SSMEs cannot provide a sufficient initial thrust-to-weight ratio (F/W) for shuttle lift-off. As a consequence, the two solid rocket motors, which is the next element of discussion, are added to the system to greatly increase the initial F/W to approximately 1.5.

1.1.c Solid Rocket Motor (SRM)

The Solid Rocket Motors, SRM's (Figure 2.4, Table 2.4), are the largest solid propellant rocket motors ever flown and the first designed for reuse [6]. Each booster is approximately 45.5 meters in length and 3.7 meters in diameter. At initial launch, one booster is approximately 585,841 kg, with 87,060kg being inert mass and 498,781 kg being solid propellant. Each booster has primary elements consisting of the motor, structure, separation systems, operational

flight instrumentation, recovery avionics, pyrotechnics, deceleration system, thrust vector control system and range safety destruct system [6]. Of greatest concern for this investigation is the motor and structure elements, and as a result the details of the SRM's construction and design are ignored. These two elements are primary driving factors in section 3. In addition, since the SRM's themselves will not be altered in any fashion, with the exception of attachment to the external tank, only the relevant information (i.e. thrust, mass, etc.) is addressed in this section.

The main characteristics (table 2.4) of concern for the structure and motor elements are the thrust, mass, specific impulse, burn time, and structural purposes. Each booster has the capability of 11.8 million Newtons of thrust and 242 seconds of Isp (268.6s in vacuum) at initial

lift-off. Special note, however, is made 50 seconds after lift-off; at this point in the ascent phase, the thrust is reduced by almost 1/3 the initial value to prevent overstressing the vehicle during maximum dynamic pressure [6]. This reduction of thrust is of significant when developing the designs in section 3. As previously mentioned, the motor houses 498,781 kg of a propellant mixture consisting of

ammonium perchlorate (oxidizer), aluminum (fuel), iron oxide (catalyst), a polymer (a binder holding the mixture together), and an epoxy curing agent. The structure has a mass of 87,060 kg and serves several purposes besides housing the propellant, one of which is carrying the entire weight of the external tank and orbiter and transmitting the weight load to the mobile launcher platform. This fact is of vital interest in any of the designs where the SRM's are eliminated. In addition to the above characteristics, the burn time is very important to the later

staging that occurs in these later sections. On the current STS missions, the SRM's burn for approximately the first 2 minutes of ascent, at which time they separate from the external tank at their two attachment points on the aft frame and forward end of the boosters.

The SSME's alone cannot lift the shuttle off the ground, and as a result the 2 boosters are required. The boosters' short-comings occur in the low Isp and controllability. From equation 2.1, the low 242s Isp affects the over-all 269s Isp of the first stage (SRM & SSME parallel combination) by reducing the high 454s Isp of the SSME's. In addition, the SRM's utilize solid propellant. The major characteristics of solid propellants are that they are not restartable, and

once they are ignited they burn until the propellant is gone.

1.1.d External Tank

Equally as important as the previous elements, but essential to Space Shuttle Main Engine operation is the external tank, ET (Figure 2.5,

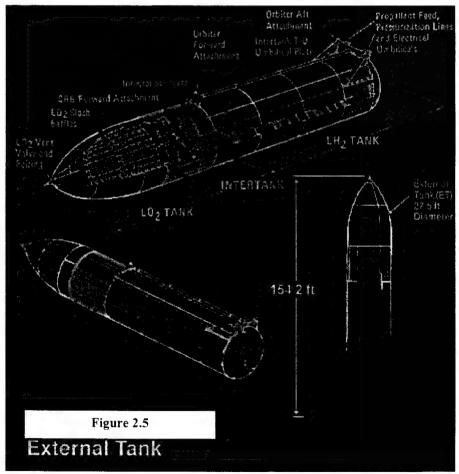

Table 2.5). The ET is the largest and heaviest element of the space shuttle, costing approximately 30 million dollars, and being the only disposable structure of the Space Transportation System. It consists of three major components: the forward liquid oxygen tank, the mid intertank housing the main electrical components, and the aft liquid hydrogen tank [7]. Of immense concern to this paper are the dimensions and volume, and the amount of propellant contained within the ET. In addition, the means by which the propellant is transported into the orbiter and thus the engines requires equal consideration.

The liquid oxygen tank is located in the top or front section of the ET and is constructed as an

Externa	l Tank
(Table

m _{external-HW} (kg)	4,126.00

range of 137,895-151,684 Pa (20-22 psig). The oxygen tank feeds into a 43cm feed-line, which runs through the intertank, then outside the ET to the aft right-hand ET/orbiter disconnect umbilical [7]. The tank itself has a volume of 558.26 m3 (19,714.77 ft3), a diameter of 8.41m (331 in), a height of 15.03m (592 in), and dry mass of 5,441kg (12,000 lbs).

The Intertank is a steel/aluminum semimonocoque cylindrical structure. Its purpose is to join the oxygen and hydrogen tanks, as well as house many of the

components necessary for proper operation of the ET. It is 8.41m (331 in) in diameter, 6.85m (270 in) long, and weighs 5,487kg (12,100 lbs).

The liquid hydrogen tank is an aluminum semimonoque structure operating at 220,632-234,421 Pa (32-34 psia). Like the oxygen tank, it has a 43cm (17 in) diameter feed-line which connects to the left-aft umbilical. At the forward end of the hydrogen tank is the ET/orbiter forward attachment pod strut, and at its aft end are the two ET/orbiter aft attachment ball fittings as well as the aft SRB-ET stabilizing strut attachments [7]. The liquid hydrogen tank is 8.41m (17 in) in diameter, 29.46m (1,160 in) long, 1,512.23m3 (53,518 ft3) in volume, and has a dry weight of 13,150kg (29,000 lbs).

In addition to the main tank components, other masses are accounted for in this investigation. These components consist of the thermal protection and external hardware. Though the actual masses may vary with a modified system, this is only a top-level analysis and therefore the values presented in Table 2.5 will be the ones used in the following sections.

2.2 Turbo Pumps

The turbo pumps (Figure 2.6, Table 2.6) are the instrument by which the rocket propellants are

fed from the External Tank into the Space Shuttle Main Engines. This system consists of a low pressure oxidizer turbo pump (LPOT), high pressure oxidizer turbo pump (HPOT), low pressure fuel turbo pump (LPFT), and high pressure fuel pump (HPFT), for each engine. The

Turbo Pumps			
	Oxidizer Pump	Fuel Pump	
Low pressure

Shaft Horsepower (hp)	27,350	73,000	
Service Life (missions)	60	60	
Design Life (missions)	240	240	
Dimensions (cm)	61 X 91	56 X 112	

bulk of this information is obtained from the Space Shuttle Main Engines section of the Space

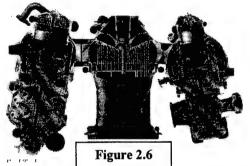

Shuttle Reference Manual [8]. Below is only a brief summary of the turbo pump operation.

This operation is very complex and tedious, refer to the aforementioned web-site for details on the turbo pumps.

2.2.a Oxidizer Turbo Pumps

The oxidizer is fed into the main propulsion system liquid oxygen feed line from the aforementioned orbiter/ET umbilical disconnect. From this point it branches out into three parallel paths leading to the LPOT of each engine. "The LPOT is an axial-flow pump driven by a six-stage turbine powered by liquid oxygen" [8]. The LPOT boosts the liquid oxygen pressure from 689,445 Pa (100psia) to an exit pressure of 2,909,587 Pa (422 psia). From the exit of the LPOT, the liquid oxygen is fed into the HPOT. The LPOT allows the HPOT to operate at high speeds without cavitation. The LPOT operates at about 5,150 rpm, and has dimensions

PRATT & WHITNEY
HIGH PRESSURE TURBOPUMPS
Line Replaceable Units for the Space Shuttle Main Engine

approximating 45.72 cm (18 in) by 45.72 cm. The LPOT's attached to the orbiters structure in a fixed position.

"The HPOT consists of two single-stage centrifugal pumps mounted on a common shaft and driven by a

two stage, hot-gas turbine" [8]. The main pump operates at 28,120 rpm and boosts the oxygen from the exit pressure of the LPOT (2,909,587 Pa, 422 psia), to 29,647,456.4 Pa (4,300psia). The liquid oxygen path then splits into several directions. One goes to fuel the LPOT turbine, one travels to the main combustion chamber, and another taps off to the oxidizer heat exchanger which is used to convert some of the oxygen into gas. This gas is used to pressurize the oxidizer

tank and also enters the HPOT second-stage preburner pump to boost the liquid oxygen to 51,159,099 Pa (7,420 psia). This gas also passes through the HPFT preburner pump. The HPOT is approximately 60.96 cm (24 in) by 91.44 cm (36 in).

2.2.b Fuel Pump

Like the liquid oxygen, the liquid hydrogen enters the orbiter and splits off into three parallel paths, which lead to the LPFT. "The LPFT is an axial-flow pump driven by a two-stage turbine powered by gaseous hydrogen" [8]. The LPFT boosts the liquid hydrogen from 206,842.7 Pa (30 psia) to 1,902,953.01 Pa (276 psia) which then feeds into the HPFT. Like the LPOT, the LPFT allows the HPFT to operate at high speeds without cavitation. The LPFT is 45.72 cm (18 in) by 60.96 cm (24 in) and operates at approximately 16,185 rpm. It too is attached to the orbiter structure at 180 degrees from the LPOT.

"The HPFT is a three-stage centrifugal pump driven by a two-stage, hot gas turbine" [8]. It is used to boost the liquid hydrogen pressure to 44,919,343.77 Pa (6,515 psia) while operating at 35,360 rpm. The outlet is then branched off into three separate paths. One path cools the combustion chamber and then feeds to run the LPFT turbine. The remaining hydrogen passes between the inner an outer wall to cool the hot-gas manifold, which is then discharged into the main combustion chamber. The second path is sent through the engine nozzle to cool it. It then joins the third flow path from the chamber coolant. This combined flow is then directed to operate the fuel and oxidizer preburners. The HPFT is 55.88 cm (22 in) by 111.76 cm (44 in).

3.0 Investigation of Pressure-fed System

3.1 Current System with Pressurant Tank

The most simplistic and cost effective approach is to simply remove the turbo pumps and replace them with a pressurant tank. This idea requires minimal change in the existing system. With this notion, the SSME's, and SRM's are not altered. In addition, the launch profile and sequence is not modified.

The basic idea is to have the turbo pumps removed from the orbiter. Then a pressurant tank and pressurant are added to the ET. Through the use of the pressurant, the oxidizer and fuel are pushed through the plumbing from the ET into the engines on the orbiter. Because of the simplicity of the idea and lack of modification in the existing system, the new system will require little design and testing. In addition, the only thing being altered is the propellant feed method, therefore the engines and boosters remain the same. As a result, the over all launch portion of the mission profile does not change. However, with the addition of the pressurant tank, the external tank's geometry and size is altered.

In the following sub-sections the investigation of this idea is explained in detailed. A conclusion is made on the feasability of this notion. The process for obtaining this conclusion is described, along with the equations used and the resultant values.

3.1.a Pressurant Mass and Volume Determination

To begin, the values of the current system's liquid propellant masses and flow characteristics are obtained from Tables 2.2-2.6. The values that are of greatest concern are the liquid oxygen and

liquid hydrogen masses, volume, and flow rates. With this information, the pressurant mass and volume are determined using Algorithm 3.1. The following algorithm is from the class notes for ASE 521 at the University of Colorado at Colorado Spring by Captain Michael Bettner [4].

Algorithm 3.1: Pressurant (Vol_{OX}, Vol_{LH}, $p_{initial}$, p_{final} , $T_{initial} \Rightarrow Vol_{press}$, m_{press})

- 1. Assume pressurant tank volume $(Vol_{press tank}) = 0$
- 2. Estimate volume of pressurant (Vol_{press})
 - Start with enough to fill all tanks +5% extra
 - $Vol_{press} = (Vol_{OX} + Vol_{LH} + Vol_{press tank}) * 1.05$ (equation 3.1)
- 3. Select initial temp (T_{initial}), initial pressure (p_{initial}), and final pressure (p_{final}) for the pressurant; the final pressure is equal to the HPOT outlet pressure plus a small margin for dynamic pressure drop and losses due to plumbing. The temperatures must be above the critical temperature to guarantee that the propellant remains a liquid.

$$T_{final} = T_{initial} \left(\frac{p_{final}}{p_{initial}} \right)^{\frac{\gamma - 1}{\gamma}} \quad \text{(equation 3.2)}$$

4. Use isentropic relationship to find the final temperature ($T_{\mbox{\tiny final}}$)

$$m_{press} = \frac{p_{final} Vol_{press}}{RT_{final}}$$
 (equation 3.3)

- 5. Use ideal gas law to determine the mass of the pressurant
- 6. Use equation 3.3 at T_{initial} and P_{initial} to find Vol_{press tank} to hold mass of pressurant
- 7. Go back to step two with Vol_{press tank} until it converges

3.1.b Tank Sizing

Tank mass sizing can be performed by two methods. The first approach is called Hoop Stress.

This method utilizes material strength, and burst pressure (MEOP, burst pressure, times a factor of safety). The second approach is an empirical method using pressure, volume, and a tank

factor (ϕ_{tank}). This tank factor is usually supplied by the manufacturer and is determined by the tank material. Table 3.1 lists some tank factors for some of the common propellant tank materials. For this

Common Tank F (Table 3.1	
metallic	2,500
graphite composite	10,000
graphite composite -T1000G [9]	50,000

investigation and all those to follow, the tank sizing is determined using method 2, the tank factor approach. For this approach, the following equation is used to determine the tank masses:

$$m_{\text{tank}} = \frac{p_b Vol_{tot}}{g_o \varphi_{\text{tank}}}$$
 (equation 3.4)

In this equation, the pressure is the burst pressure (pressure of system plus a safety factor) for the tanks. However, an exception is made for tanks made of titanium; the tank factor for titanium already includes a factor of safety equal to 2. In this section as well as in the following sections, tanks consisting of either titanium or composites are considered. These materials are chosen for their high tank factors, as seen in Table 3.1. One might ask why the material with the highest tank factor is not always used. The reasons are many (cost is a large factor), but for this situation one of the limiting factors is the propellants. The propellants for this situation are cryogenic (operating at very low temperatures); this can hinder the use of some composites. As

of 1995, "the use of composite tank materials has not been demonstrated for cryogenic propellants because of concern for brittleness" [5]. Because of this aforementioned situation, composite materials are used only for the pressurant tank.

As for the geometry of the tanks, they are modeled as spheres. This is initially done for this investigation, as well as the following investigations for simplicity sake. Once a method is found that works within the mass limitations, the tanks will be modeled as cylinders, which is more complicated but is more common for tanks of this size.

3.1.c Optimizing Pressurant Mass

Now that the process for determining pressurant mass and volume and tank size and mass has been addressed, the method by which an optimal solution is achieved can be presented. To begin, the situation presented in this section has both fixed propellant volume and mass. As a result, the volume of the propellant tanks is predetermined. On the contrary, the mass and the volume of the pressurant can be altered through variation in initial pressurant tank pressure (p_{initial}) as an increase in final pressure. In order to find the optimal solution, varying p_{initials} are implemented in conjunction with Algorithm 3.1 and Equation 3.4. These calculations for various pressurants and tank materials are displayed in Tables B.1-B.6 and Charts B.1-B.6 in Appendix B. The reason for testing several pressurants over a range of increasing initial pressures is simple. First, by increasing the initial pressure of the pressurant one can reduce the volume and hence, the mass of the pressurant. From Equation 3.4, reducing the volume of the pressurant reduces the pressurant tank size, which in-turn decreases the mass of the tank. However, the increase in pressure will require a thicker tank wall—increasing the tank mass (see

equation 3.4). This problem is not great, for the reduction in volume due to increase in pressure out-weighs the increase in wall-thickness.

The reasoning behind testing different pressurants is simple as well. Because of the various specific heat ratios (γ) and molecular weights (M), some elements are more optimal than others in the current situation. Among the most commonly used pressurants include Helium (He), Argon (Ar), and Nitrogen (N₂), and are the three different pressurants investigated in each section. Note should be made that a pressurant needs to be inert; a pressurant cannot react with the propellants or the storage tanks.

3.1.d Results

As previously mentioned, several combinations of tank materials and pressurants are tested. The best results (Table 3.2) occur for propellant tanks made of titanium with helium as the pressurant. As for the pressurant tanks, a composite material works best, and two types are used. One has a tank factor of 10,000 meters (denoted situation 1) and the other has a tank factor of 50,000 meters (denoted situation 2). As for the initial pressure of these possible situations, the best solutions occur at a p_{initial} of 277,169,245 Pa (40,200 psi) for both situations. This results in a tank mass of 3,889,790.17 kg (8,578,448.8 lbs) for situation 1 and 777,958.03kg (1,715,689.8 lbs) for situation 2.

Now that the tank and pressurant masses are known, these values must be compared and implemented into the current system to check for feasibility. The easiest way to check this

feasibility is to see if the new tank system weighs the same as the old, or that the inert mass and inert mass fraction for each system are the same. Table 3.4 shows a rough comparison of all of the systems' pressurant system masses (a detailed mass breakdown is located in Table B.7-B.13, Appendix B). As viewed in Table 3.4, one can see that the modified system weighs much more

Pressurant Test Summary Table 3:4				
Pressurant	Helium	Nitrogen	Argon	Current System
Optimal pinitial (Pa)	277,169,245.00	343,689,863.80	277,169,245.00	
m _{pressurant} (kg)	616,216.57	3,234,838.23	6,216,035.63

ΔV _{tot} (m/s)	795.9130161	645.6914563	442.2510007	9,086
F/W _{lift-off-1}	0.376008828	0.313206208	0.222445236	1.5
F/W _{lift-off-2}	0.097164998	0.078404009	0.053275382	
φ _{tank} =50,000m				
m _{tank} (kg)	777,958.03	581,730.09	785,514.28	
m _{launch} (kg)	5,054,539.24	7,476,932.95	10,661,914.54	2,040,469
ΔV _{tot} (m/s)	1433.657314	882.5220218	587.6493267	9,086
F/W _{lift-off-1}	0.607499038	0.410680121	0.287999657	1.5
F/W _{lift-off-2}	0.178197311	0.108050911	0.0712001	

than the current system. This can be attributed to the pressurant tank and the pressurant mass itself. The pressurant is considered inert mass and remains with the system for the duration of the launch. This situation puts a great burden on the launch capability of the system.

To gain a better idea of how this pressurant system limits the launch capability, the change in velocity (ΔV) for the modified system is calculated using the ideal rocket equation (equation 3.5) and compared to the required ΔV .

$$\Delta V = I_{sp} g_o \ln \left(\frac{m_i}{m_f} \right) \qquad \text{(equation 3.5)}$$

Once again it is seen that large inert mass due to the pressurant and the tanks greatly reduces the total ΔV to 795.91 m/s for situation 1 and 1433.66 m/s for situation 2. These values are well below the required ΔV of 9,086 m/s [5].

Another characteristic of great importance is the thrust-to-weight ratio, F/W, for each stage. If the F/W is less than one, the system will never lift off. In addition a margin for losses (i.e. drag) should be included which increases the F/W to about 1.5 for the shuttle at lift-off. As demonstrated by the values in Table 3.4, none of the test systems can even get off of the launch pad. The best F/W is .607 for stage 1 situation 2 with helium pressurant. In addition, an interesting fact is noted; because of the large amount of inert mass (pressurant and tank) that remains with the shuttle throughout launch, the F/W becomes greatly reduced at the beginning of stage 2 (after SRM separation).

Based on the aforementioned material, this method of simply replacing the turbo-pumps with a pressurant tank does not work. The three tanks, fuel tank, oxidizer tank, pressurant tank, provide a large source of inert mass as a result of the required high chamber pressure of the SSME's. In addition, even if the tanks themselves had an outstanding tank factor (low mass) the pressurant needed to fill all the tanks and maintain an operating pressure is extremely high. The pressurant accounts for a large portion of the inert mass, which cannot be reduced unless the tank volumes are reduced. This was done through pressure optimization for the pressurant tank. However, the propellants are liquids and their volumes cannot be simply reduced by increasing

the tank pressure. The amount of propellant must be reduced in order to reduce the tank volumes. This is possible by staging the shuttle launch system. This is the topic of the next sections.

3.2 Staging STS

This next section presents a possible solution that was present in the previous section. How can the volume of the propellant tanks be reduced. One possible solution is staging the current system. By staging the launch system, the amount of propellant needed to obtain the required ΔV can be reduced. Various staging methods will be performed to investigate the feasibility of the idea. One drawback of this solution is the need for research, development, design, and testing of the new system. In addition, staging the system in a manner different than the current system adds complexity.

Once again, the constraints include no modification to the SRM's or to the orbiter. In addition, the payload capability cannot be reduced to allow for an increase in launch system mass.

The process by which this staging method is tested is very simple, and is utilized in the follwing sections to test the different situations. The process is explained in Algorithm 3.2.

Algorithm 3.2: Mass (Isp,
$$m_{pay}$$
, ΔV_{tot} , $f_{inert} \Rightarrow m_I$, m_f , m_{prop} , m_{inert} , F/W)

1. Choose a reasonable inert mass fraction, f_{inert} , where:

$$f_{inert} = \frac{m_{inert}}{m_{inert} + m_{prop}}$$
 (equation 3.6)

• Usually $f_{inert} = 0.06$ to 0.20 for most systems.

2. Find propellant mass, m_{prop}, from equation 3.7:

$$m_{prop} = \frac{m_{pay} \left(e^{\left(\frac{\Delta V_{lot}}{I_{sp} g_o} \right)} - 1 \right) (1 - f_{inert})}{1 - f_{inert} e^{\left(\frac{\Delta V}{I_{sp} g_o} \right)}}$$
 (equation 3.7)

3. Using f_{inert} and m_{prop} , find the inert mass, m_{inert} , from equation 3.8:

$$m_{inert} = \frac{f_{inert}}{1 - f_{inert}} m_{prop}$$
 (equation 3.8)

- For this investigation, m_{inert} includes the mass of the propellant tanks, intertank, external hardware, and thermal protection; the SSME's are not included, for they are a part of the payload (orbiter mass).
- 4. Find the initial mass, m_i, and the final mass, m_f, using equations 3.9 and 3.10, respectively:

$$m_i = m_{pay} + m_{inert} + m_{prop} = m_f + m_{prop}$$
 (equation 3.9)
 $m_f = m_{pay} + m_{inert}$ (equation 3.10)

5. With the initial mass, calculate the initial thrust-to-weight ratio, F/W:

$$\frac{F}{W} = \frac{T}{m_i g_o}$$
 (equation 3.11)

 Ensure that the F/W is greater than 1, otherwise the vehicle cannot liftoff. To account for losses (i.e. drag), a F/W of 1.3-1.5 is preferred (the current shuttle system is approximately 1.5)

3.2.b SRM's in Series with SSME's

One possible staging method is based on the fact that engines firing in series (basic staging method) is more efficient than engines firing in parallel (SRM's and SSME's firing together). With this approach, a saving is made. Once again, there are a couple of constraints:

- 1. The SRM's and orbiter are not modified in any way.
- 2. The Propellants for the SSME's are Liquid Oxygen and Liquid Hydrogen
- 3. For stage one, the $F/W \ge 1.3$; for the following stages (stage 2a & 2b), $F/W \ge 1.3$.

These constraints are few, but very limiting. In addition, one more major thing is considered; the modified system needs to remain simple; this reduces complexity and cost due to design and testing.

To determine the validity and possibility of this staging solution, a modified version of Algorithm 3.2 is utilized. To begin, the total propellant mass, $m_{prop-SRM-tot}$, and specific impulse at sea level, Isp_{SRM} , are obtained from Table 2.4. With these values and equations 3.5, 3.9, and 3.10, the payload mass, m_{pay} , is determined for fractions of ΔV contributed by stage one. Looking at Table C.3 and Chart C.3 in the Appendix B, the $\Delta V_{1-fract}$ for the optimal m_{pay-1} is chosen. However, the best $\Delta V_{1-fract}$ must chosen with some consideration. As previously mentioned, the F/W must be greater than or equal to 1.30 for stage one. And judging from Table C.3 and Chart C.3, the best solution occurs for $\Delta V_{1-fract}$ equal to .01, which will not help the

situation at all. Therefore, $\Delta V_{1-\text{fract}} = 0.20$ is the best choice (this is where F/W=1.30). At this point $\Delta V_1 = 1,846$ m/s, $\Delta V_2 = 7384$ m/s, and $m_{\text{pay-1}} = 673,996$ kg.

Once the $\Delta V_{1-\text{fract}}$ is chosen, ΔV_2 is calculated from the ΔV_{tot} - ΔV_1 . With the total change in velocity required by the second stage, ΔV_2 , and the mass limitation of the second stage, an optimization is performed. Using Algorithm 3.2 and starting with stage 2b, the initial mass, mi 2h is calculated for this stage. In this situation, the payload is the aforementioned orbiter and its payload. The initial mass for stage 2b is then, used for the payload mass of stage 2a, m_{pay-2a}. Once again, Algorithm 3.2 is utilized. This scenario is repeat over a range of ΔV fraction for stage 2a, $\Delta V_{2a\text{-fract}}$. The optimal solution is chosen for stage 2 based on the results in Table C.4 and Chart C.4. Four main things are considered when choosing the best solution: F/W_{2a}, F/W_{2b}, and m_{i-2a} , and the f_{inert} for each stage. The thrust-to-weight ratios must be at least 1.30. In addition, the initial mass for stage 2a can not exceed the payload mass allowed by stage 1. Finally an finer must be chosen that allows a possible solution. For this case, the highest possible finert that allows a solution is 0.04 for stage 2a and 0.05 for stage 2b. Although this is not a good choice (a much higher f_{inert} is better, possibly $f_{inert} = 0.20$), it is the best one which still allows some viable answer. Looking at Chart C.4, and taking into account the trends and slopes of each variable, the best solution occurs for $\Delta V_{2a} = .56$. This choice provides an $m_{i-2a} = 637,756$ kg, a $F/W_{2a} = 1.04$, and a $F/W_{2b} = 2.86$. The initial mass is within the limits, as well as the F/Wfor stage 2b. However, the finert for each stage is very low, and the F/W for stage 2a is also well below the requirement.

Without even calculating the tank masses and sizes for this situation, it is determined that this situation will not work. This is mainly because of the F/W of stage 2a and the inert mass fractions. As seen from Section 3.1, the pressurant tank and pressurant would devour the inert mass alone. This solution is the best thus far, but falls short of staying within the constraints.

3.2.c SRM's in Series with SSME's with Added Engines

This next option is similar to the situation presented in the previous section; in this situation an engine is added to 2a. This option increases the F/W of the stage, but at the same time increases the complexity. To minimize this complexity, the SSME engines are used. Using the same process utilized in section 3.2.b and maintaining the same ΔV fraction between stages 1 and 2, the best answer is determined and illustrated in Table 3.7 for stages 2a and 2b. Detailed tables

and charts are located in Appendix C (Table C.3 & C.5, Chart C.3 & C.5).

Once again, the f_{inert} appears to be the limiting factor of this situation. The

Table 3.72 -5				
	Stage 1	Stage 2a	Stage 2b	
ΔV_{fract}	0.20	0.41	0.59	
∆V (m/s)	1,846.00	3027.44	4,356.56	
m _{prop} (kg)	997,562.00	328,633.09	193,231.66	
m _{inert} (kg)	174,120.00	28,576.79	12,333.94	
m _i (kg)	1,845,678.84	667,275.48	310,065.59	
m _f (kg)	848,116.84	338,642.38	116,833.94	
F/W	1.30	1.328625212	2.14	

highest finert's possible, while

maintaining the initial mass limit (determined by stage 1, see section 3.2.b), were 0.08 and 0.06 for stages 2a and 2b, respectively. The initial mass and F/W for both stages are within the limitations. However, this situation will most likely not work because of the limiting inert mass, and is tested much the same way as in section 3.1

Using the same steps as in section 3.1, the tank masses and pressurant mass are calculated (Tables C.6 & C.7). With these tank masses, and the known thrusts and Isp's, the F/W and ΔV for each stage is calculated (Table C.8). Looking at the values within Table C.8, it is seen that the overall ΔV is only 2,097 m/s, which is well short of the 9,230 m/s. In addition, the F/W for each stage is never greater than 1, much less the required 1.3.

As a result, the system investigated in section 3.2.c has potential, but once again is greatly limited by the high inert mass of the tanks and pressurant. The delta V and F/W fall very short of the required amounts.

4.0 Conclusion

Pressure feeding the space shuttle main engines might first appear to be any easy solution to reducing the complexity and cost of the current turbo pump system. However, from the calculations and their resultant values, it is determined that this system is not a viable solution. Pressure systems, especially for large launch systems like the STS have a major disadvantage, the pressurant mass and tank masses. As a result of the high pressure required to operate the SSME's, the propellant tanks and pressurant tank must be able to contain very high pressure liquids. Because of this, the tanks and must be very thick, hence contributing to a large inert mass. In addition, the pressurant used, must be able to fill all of the tanks while still maintaining the required operating pressure throughout the duration of SSME operation. This necessity contributes to the inert mass of the system through the large amount of pressurant or pressurant mass. In conclusion, the system proposed and investigated within this report is not plausible.

For this system to work within the constraints, both higher tank factors and high thrusting boosters must be developed.

Some possible further investigation in this area might include looking into pressurizing the rocket propellants through their own vapor pressure. This would add propellant mass, however, the pressurant and pressurant tank would be totally eliminated. Another possible solution would be to reduce the operating pressure of the SSME's. Consequently, the nozzle throat would increase and a small hit in Isp might result. These options, though, are some alternative solutions that could be investigated.
